Material: Lectures 1-3 **Due:** Start of Lecture 5: Tuesday, 9 June by 2pm EDT

Submission notes:

- For full credit, please show your work and denote your answers with a circle or a box.
- Always write and draw your diagrams neatly! We cannot be expected to GUESS what you meant to write!
- Please see the submission guidelines on the homework page of the course website for details.
- 1. (5 pts) Answer the following questions regarding execution of loops. Assume that the code below is executed on an MSP430 (ie, an int has a size of two bytes).
 - **a.** In the following code segment, how many times does the loop iterate? What are the values of kk, mm, and inVal (in decimal) at the end of the first and last loops?

```
unsigned int inVal, out, kk = 0x0001, mm = 0x1000;
char count = 1;
// ...
while(kk != 0)
{
    inVal = (mm + kk) / kk;
    // . . .
    mm /= 2;
    kk = kk << 1;
}
// ...
```

(continued on the next page)

- **2.** (10 pts) In a table like the one below, show how the following variables would be stored successively in memory by:
 - A Little-endian CPU
 - A Big-endian CPU

- **a.** First, determine the representation of each variable listed above in hex.
- **b.** Next, arrange the variables as they would be stored in memory starting at address 0x4200. To do this, make a table similar to the one below, labeling each address and denoting which byte would be stored in that address in each case. Remember that each address in memory holds 1 byte.

Address	Little Endian	Big Endian
0x4202		
0x4201		
0x4200		

Note: This table is usually drawn with the lowest memory address at the *bottom* of the table, as shown here:

- c. Is the MSP430 architecture we use in class big or little endian?
- **d.** What if we added one additional variable in the example above as shown below. Based on only the code below, what is the value of new_var? How is it arranged in memory?

```
// ...
long unsigned int count = 16486; // Last variable from above
unsigned int new_var;
```

3. (5 pts) **Debugging challenge:** Consider the code example below. This program is designed to compare the contents of two arrays: if they are equal, the program should display "TRUE," if the arrays are not equal, the program should display "FALSE".

However, even when the arrays have the same value, the program always prints "FALSE", regardless of the values in arrays a and b.

What is going on here? What about the program causes the comparison to always fail?

```
int a[4] = {1, 2, 3, 4};
int b[4] = {1, 2, 3, 4};
if (a == b) {
    display("TRUE");
else {
    display("FALSE");
}
```

If you would like to run this program (not required), you can find a CCS project containing this example listed with the homework document on the course website. To run the project, download and import the zip file into CCS in the same manner as you did for the lab 0 demo project (see the lab 0 assignment for instructions).
